

THE POLYNOMIAL ANALOGUE OF A THEOREM OF RÉNYI

KENT E. MORRISON

ABSTRACT. Rényi's result on the density of integers whose prime factorizations have excess multiplicity has an analogue for polynomials over a finite field.

Let $n = p_1^{\alpha_1} \cdots p_r^{\alpha_r}$ be the prime factorization of a positive integer n . Define the **excess** of n to be $(\alpha_1 - 1) + \cdots + (\alpha_r - 1)$, which is the difference between the total multiplicity $\alpha_1 + \cdots + \alpha_r$ and the number of distinct primes in the factorization. An integer with excess 0 is also said to be **square-free**. Let E_k denote the set of positive integers of excess k , $k = 0, 1, 2, \dots$. Rényi proved that the set E_k has a density d_k and that the sequence $\{d_k\}$ has a generating function given by

$$\sum_{k \geq 0} d_k z^k = \prod_p \left(1 - \frac{1}{p}\right) \left(1 + \frac{1}{p - z}\right),$$

where the product extends over the primes. Recall that the density of a set of positive integers E is the limit, if it exists,

$$\lim_{n \rightarrow \infty} \frac{\#(E \cap \{1, 2, \dots, n\})}{n},$$

which is the limiting probability that an integer from 1 to n is in E .

The set of square-free integers is E_0 and setting $z = 0$ in the generating function gives $d_0 = \prod_p (1 - 1/p^2)$, which is the well-known result that the density of square-free integers is $1/\zeta(2) = 6/\pi^2$. (This was first proved by Gegenbauer [2] in 1885. A clear, non-rigorous presentation is in [3].) By setting $z = 1$ one sees that $\sum_k d_k = 1$, so that the density is countably additive on the specific partition of $\mathbf{Z}^+$ given by the E_k . Rényi's proof appeared in [7], but an alternative proof was given by Kac in [4, pp. 64–71].

The aim of this paper is to derive an analogue of the generating function for polynomials in one variable over a finite field. Let $\mathbf{F}_q$ be the field with q elements and $\mathbf{F}_q[x]$ the polynomial ring. The prime elements of $\mathbf{F}_q[x]$ are the irreducible monic polynomials. Let f be a monic polynomial with prime factorization $f = \pi_1^{\alpha_1} \cdots \pi_r^{\alpha_r}$, and define the excess of f to be $(\alpha_1 - 1) + \cdots + (\alpha_r - 1)$ just as for an integer. Let $e_{n,k}$ be the number of monic polynomials of degree n and excess k . Define

$$d_{n,k} = \frac{e_{n,k}}{q^n},$$

which is the probability that a monic polynomial of degree n has excess k . Note that $d_{0,k} = 0$ for $k > 0$. Then define the analogue of the density to be the limiting “probability” as the degree goes to infinity

$$d_k = \lim_{n \rightarrow \infty} d_{n,k}.$$

Define $D(z) = \sum_{k \geq 0} d_k z^k$ to be the ordinary power series generating function of the sequence $\{d_k\}$. Let $Nf = q^{\deg f}$ be the norm of the polynomial f , which is the cardinality of the residue ring $\mathbf{F}_q[x]/(f)$. The main result of this paper is the following theorem concerning $D(z)$.

Theorem 1. *The generating function $D(z)$ has a factorization over the prime polynomials given by*

$$D(z) = \prod_{\pi} \left(1 - \frac{1}{N\pi}\right) \left(1 + \frac{1}{N\pi - z}\right).$$

Proof. We begin with the geometric series

$$\frac{1}{1 - qt} = \sum_{n \geq 0} q^n t^n,$$

which is the generating function for the number of monic polynomials of degree n . Then unique factorization in $\mathbf{F}_q[x]$ allows us to factor the generating function formally

$$\begin{aligned} (1) \quad \frac{1}{1 - qt} &= \prod_{\pi} \sum_{j \geq 0} t^{j \deg \pi} \\ &= \prod_{\pi} \frac{1}{1 - t^{\deg \pi}}. \end{aligned}$$

By grouping the primes of the same degree and letting ν_i denote the number of primes of degree i , we can rewrite the last line above as

$$\frac{1}{1 - qt} = \prod_{i \geq 1} \left(\frac{1}{1 - t^i} \right)^{\nu_i}.$$

From this it follows that

$$(2) \quad 1 - qt = \prod_{i \geq 1} (1 - t^i)^{\nu_i}$$

as a formal power series. In the product on the right there is a finite number of terms for each power of t so that the coefficients make sense. In fact, the coefficient of t^n is 0 except for $n = 0, 1$. However, considered as a function of a complex variable t , the product does not converge for all t . It does converge absolutely for $|t| < 1/q$. This follows from consideration of the series $\sum \nu_i t^i$ and the fact that ν_i is asymptotic to q^i/i .

Next we define the two-variable generating function

$$E(t, z) = \sum_{n, k} e_{n, k} t^n z^k.$$

Modifying the factorization in (1), we see that

$$E(t, z) = \prod_{\pi} (1 + t^{\deg \pi} z + t^{2 \deg \pi} z^2 + \dots + t^{j \deg \pi} z^{j-1} + \dots).$$

Notice that the variable z appears with a power that is equal to the excess multiplicity. That is, if $f = \pi_1^{\alpha_1} \dots \pi_r^{\alpha_r}$ then the product expansion of $E(t, z)$ has a term

of the form $t^{\alpha_1 \deg \pi_1} \dots t^{\alpha_r \deg \pi_r} z^{\alpha_1 - 1} \dots z^{\alpha_r - 1}$. Sum the geometric series in each factor to obtain the formal factorization

$$E(t, z) = \prod_{\pi} \left(1 + \frac{t^{\deg \pi}}{1 - t^{\deg \pi} z} \right).$$

Group the irreducibles by degree to get

$$(3) \quad E(t, z) = \prod_i \left(1 + \frac{t^i}{1 - t^i z} \right)^{\nu_i}.$$

Now the product on the right converges absolutely if and only if the series

$$(4) \quad \sum_{i \geq 1} \nu_i \left| \frac{t^i}{1 - t^i z} \right|$$

converges. We claim that (4) converges for $|t| < 1/q$ and $|z| < q$, because the denominators $|1 - t^i z|$ are bounded away from 0 and ν_i is asymptotic to q^i/i . (Actually, it suffices that $\nu_i < q^i$.)

From (2) and (3) we get

$$(1 - qt)E(t, z) = \prod_{i \geq 1} (1 - t^i)^{\nu_i} \prod_{i \geq 1} \left(1 + \frac{t^i}{1 - t^i z} \right)^{\nu_i}.$$

On the domain where both products converge absolutely we can combine the factors for each i to get

$$(5) \quad (1 - qt)E(t, z) = \prod_{i \geq 1} (1 - t^i)^{\nu_i} \left(1 + \frac{t^i}{1 - t^i z} \right)^{\nu_i}.$$

By multiplying the factors together we can see that the absolute convergence of the infinite product depends on the convergence of the series

$$\sum_i \nu_i \left| \frac{t^{2i} z - t^{2i}}{1 - t^i z} \right|.$$

Then reasoning along the same lines as before we see that this series converges for $|t^2| < q$ and $|z| < \sqrt{q}$. In particular, the product converges for $t = 1/q$, and so after carrying out the multiplication of the left side of (5) we arrive at

$$\sum_{n,k} (e_{n,k} - qe_{n-1,k}) t^n z^k = \prod_{i \geq 1} (1 - t^i)^{\nu_i} \left(1 + \frac{t^i}{1 - t^i z} \right)^{\nu_i}.$$

We evaluate this at $t = 1/q$ to get

$$\sum_{n,k} (e_{n,k} - qe_{n-1,k}) (1/q)^n z^k = \prod_{i \geq 1} (1 - (1/q)^i)^{\nu_i} \left(1 + \frac{(1/q)^i}{1 - (1/q)^i z} \right)^{\nu_i}.$$

The coefficient of z^k is the sum $\sum_{n \geq 1} (e_{n,k}/q^n - e_{n-1,k}/q^{n-1})$. This telescopes to give

$$\lim_{n \rightarrow \infty} \frac{e_{n,k}}{q^n} = \lim_{n \rightarrow \infty} d_{n,k},$$

which is the definition of d_k , and so we have

$$D(z) = \sum_k d_k z^k = \prod_{i \geq 1} (1 - (1/q)^i)^{\nu_i} \left(1 + \frac{(1/q)^i}{1 - (1/q)^i z} \right)^{\nu_i}.$$

Finally, we write the product by indexing over the prime polynomials π and note that the norm of π is $N\pi = q^{\deg \pi}$. With this we have the generating function for the d_k in the form that is most directly analogous to Rényi's theorem.

$$\begin{aligned} D(z) &= \prod_{\pi} (1 - (1/q)^{\deg \pi}) \left(1 + \frac{(1/q)^{\deg \pi}}{1 - (1/q)^{\deg \pi} z} \right) \\ &= \prod_{\pi} \left(1 - \frac{1}{N\pi} \right) \left(1 + \frac{1}{N\pi - z} \right). \end{aligned}$$

□

The coefficient d_0 is the limiting “probability” that a monic polynomial is square-free. To develop the analogy with the density of the square-free integers given by d_0 in Rényi's generating function, we use the zeta function of $\mathbf{F}_q[x]$ (i.e. the zeta function of the affine line over $\mathbf{F}_q$)

$$\zeta(s) = \frac{1}{1 - q^{-s}},$$

which immediately comes from the definition

$$\zeta(s) = \sum_{\mathfrak{a}} \frac{1}{(N\mathfrak{a})^s},$$

where the sum is over all ideals of $\mathbf{F}_q[x]$ and the norm $N\mathfrak{a}$ is the cardinality of the residue ring $\mathbf{F}_q[x]/\mathfrak{a}$. It has a factorization over the prime ideals (i.e. irreducible polynomials)

$$\begin{aligned} \zeta(s) &= \prod_{\pi} \frac{1}{1 - (N\pi)^{-s}} \\ &= \prod_{i \geq 1} \left(\frac{1}{1 - q^{-is}} \right)^{\nu_i}. \end{aligned}$$

Corollary 1. $d_0 = \frac{1}{\zeta(2)} = 1 - \frac{1}{q}$.

Proof. We have

$$d_0 = D(0) = \prod_{i \geq 1} \left(1 - \frac{1}{q^{2i}} \right)^{\nu_i}.$$

Then in (2) we may let $t = 1/q^2$, because the product converges for $|t| < 1/q$, to obtain

$$1 - \frac{1}{q} = \prod_{i \geq 1} \left(1 - \frac{1}{q^{2i}} \right)^{\nu_i}.$$

Notice that the product is $1/\zeta(2)$. □

Corollary 1 can be obtained as a special case of much more general results on square-free values of polynomials in one or more variables from the work of Ramsay [6] and Poonen [5]. It turns out that for $n \geq 2$, the value of $d_{n,0}$ is $1 - 1/q$. This can be seen by finding the coefficients $e_{n,0}$, which count the number of monic, square-free polynomials of degree n . These polynomials can be counted directly; see, for example, [1].

Corollary 2. *The number of square-free monic polynomials of degree $n \geq 2$ is $q^n - q^{n-1}$.*

Proof. The generating function $\sum_{n \geq 0} e_{n,0} t^n = E(t, 0)$. From (3) we see that

$$E(t, 0) = \prod_{i \geq 1} (1 + t^i)^{\nu_i}.$$

Using (2) we see that

$$\begin{aligned} E(t, 0)(1 - qt) &= \prod_{i \geq 1} (1 + t^i)^{\nu_i} (1 - t^i)^{\nu_i} \\ &= \prod_{i \geq 1} (1 - t^{2i})^{\nu_i} \\ &= 1 - qt^2. \end{aligned}$$

Therefore,

$$E(t, 0) = \frac{1 - qt^2}{1 - qt},$$

from which it follows that $e_{n,0} = q^n - q^{n-1}$ for $n \geq 2$. $\square$

From the expression

$$D(z) = \prod_{i \geq 1} \left(1 - \frac{1}{q^i}\right)^{\nu_i} \left(1 + \frac{1}{q^i - z}\right)^{\nu_i}$$

we can see that $D(z)$ has poles at $z = q^i$ of multiplicity ν_i . In particular the pole at $z = q$ has multiplicity $q - 1$. Elementary analysis of the singularity there, along the lines of Kac [4] in his discussion of Rényi's result, enables us to describe the asymptotic behavior of the d_k as $k \rightarrow \infty$.

Corollary 3. *As k goes to infinity, d_k is asymptotic to*

$$A \frac{k^{q-2}}{q^k},$$

where the constant A is given by

$$A = \frac{1}{(q-2)!} \left(\frac{1}{q} - \frac{1}{q^2}\right)^{q-1} \prod_{i \geq 2} \left(1 - \frac{1}{q^i}\right)^{\nu_i} \left(1 - \frac{1}{q^i - q}\right)^{\nu_i}.$$

One may contrast this asymptotic result with the classical case of Rényi. Although the generating functions have clearly analogous form, the generating function for the number-theoretic version has only a simple pole $z = 2$, which is the pole of smallest absolute value. The asymptotic analysis shows that

$$d_k \sim \frac{\delta}{2^k},$$

where

$$\delta = \frac{1}{4} \prod_{p \geq 3} \frac{(p-1)^2}{p(p-2)}.$$

The referee has observed that Theorem 1 of this article can be extended naturally to function fields over finite fields by using S -zeta functions and their residues at $t = 1/q$. Let K be a function field over the constant field $\mathbf{F}_q$. Let S be a finite, non-empty set of places on K and let $\mathcal{O}_{K,S}$ denote the ring of S -integers of K .

Then for every integer $k \geq 0$, the density $d_{k,S}$ of ideals in $\mathcal{O}_{K,S}$ with excess k exists and the following analytic identity holds:

$$\sum_{k \geq 0} d_k z^k = \prod_{v \notin S} \left(1 - \frac{1}{Nv}\right) \left(1 + \frac{1}{Nv - z}\right),$$

where for each place v on K the norm $Nv = q^{\deg v}$ is the cardinality of the residue field at v .

Finally, the referee has pointed out that by generalizing Kac's proof of Rényi's theorem [4, pp. 64–71], there should also be an analogue of the theorem for the density of ideals with excess k in the ring of algebraic integers (or ring of S -integers) of any number field.
